The nature of the pseudogap phase and its relation to high- T_c cuprate superconductors remains a significant yet unresolved problem in condensed matter physics. The central question concerns whether the pseudogap is related to precursor superconductivity or other possible broken symmetry state. Irrespective of the origin, the pseudogap is universally regarded as an essential piece of the physics of unconventional cuprate superconductors. While the pseudogap in the cuprate family of high- T_c superconductors has been extensively documented, spectroscopic manifestations of the pseudogap in the iron-based materials remained elusive.

We report on the infrared studies of the ab -plane and c -axis charge dynamics of a prototypical pnictide system: the BaFe_2As_2 (Ba122) family. Our experiments have identified hallmarks of the ab -plane and c -axis pseudogap in the Ba122 system that mirror the spectroscopic manifestations of the pseudogap in the underdoped cuprates. Moreover, the evolution of the charge dynamics across the phase diagram suggests that the pseudogap is not directly related to precursor superconductivity.
