Energy and System Dependent Heavy Flavor Measurements at PHENIX at RHIC

Xuan Li (LANL)
For the PHENIX Collaboration
Outline

• Motivation

• Overview of RHIC and PHENIX

• Selected PHENIX heavy flavor measurements
  – In small systems
    • Measurement of charm and bottom via di-muon channel in p+p and p+Au collisions.
    • Forward and backward J/ψ $R_{AB}$ via di-muon channel in p+Al, p+Au and He$^3$+Au collisions.
    • Single muon $v_2$ from heavy flavor decays in d+Au collisions.
  – In heavy ion collisions
    • Mid-rapidity B/D $R_{AA}$ and $v_2$ via single electron channel in Au +Au collisions.

• Summary and Outlook
Motivation

• Heavy flavor production is an ideal probe to study the full evolution of the medium as it is produced in the early stage of nuclear collisions due to its high mass \( m_c/m_b >>> \Lambda_{QCD} \).

• Disentangle different heavy flavor production mechanisms at RHIC energies.

Open Heavy Flavor production

![Graph showing open heavy flavor production at various scales and energies.](image)
Heavy Flavor Production in Heavy Ion Collisions

- Not well understood about interaction with the medium.

- **Cold Nuclear Matter (CNM) effect:**
  - Nuclear modification of PDFs.
  - Cronin/EMC effect.
  - Energy loss of partons traversing nucleus (Initial state).
  - Breakup of charmonium before exiting nucleus.
  - Co-mover absorption for quarkonia.

- **Hot nuclear matter effect:**
  - Energy loss of partons traversing QGP.
  - Color screening.
  - Coalescence of quarkonia in QGP.

- Need to measure multiple observables in different processes to isolate the **initial/final state and cold/hot nuclear matter effects.**
Overview of RHIC

- The versatility of RHIC operation allowed us to collect data in various collision systems: p+p, p+Al, p+Au, d+Au, He$^3$+Au, Cu+Cu, Cu+Au, U+U, Au+Au.
Overview of the PHENIX detector

- PHENIX had electron ID detectors at mid-rapidity and muon ID detectors at forward/backward rapidity.
- The silicon vertex detectors: **VTX** and **FVTX** made new heavy flavor measurement possible in small systems and Au+Au collisions.

  - **VTX**:
    - With $|y|<1.2$ and $\phi\approx2\pi$ coverage.
    - Provide precise vertex and tracking for $D,B \rightarrow X+e$ measurements.

  - **FVTX**:
    - With $1.2<|y|<2.2$ and $\phi=2\pi$ coverage.
    - Provide precise tracking and improved mass resolution for $J/\psi, B \rightarrow J/\psi$ and $D, B$ separation measurements.
Heavy flavor measurements in small systems

• to understand the production mechanism
• to study the cold nuclear matter (CNM) effects
• to explore the formation of QGP droplet? Flow?
Di-muon correlations ($1.2 < |y| < 2.2$) in 200 GeV p+p collisions

- Unlike-sign and like-sign di-muon correlations with template fit and comparison with PYTHIA Tune A (POWHEG) models suggests the charm production in 200 GeV p+p collisions is dominated by flavor excitation.

**PHENIX** (a) $pp \rightarrow c\bar{c} X \rightarrow \mu^+\mu^- X$

- $p_\mu > 3$ GeV/c, $1.2 < |y| < 2.2$
- $1.5 < m_{\mu^+\mu^-}$ [GeV/c²] $< 2.5$
- Global Uncertainty 12.0%

**PHENIX** (a) $pp \rightarrow c\bar{c} X \rightarrow \mu^+\mu^- X$

- $p_\mu > 3$ GeV/c, $1.2 < |y| < 2.2$
- $1.5 < m_{\mu^+\mu^-}$ [GeV/c²] $< 2.5$
- Global Uncertainty 12.0%
Di-muon correlations ($1.2 < |y| < 2.2$) in 200 GeV p+p collisions

- Unlike-sign and like-sign di-muon correlations with template fit and comparison with PYTHIA Tune A (POWHEG) models suggests the **bottom production** in 200 GeV p+p collisions is dominated by flavor(pair) creation.
Di-muon correlations (1.2<|y|<2.2) in 200 GeV p+Au collisions

- Use like-sign di-muon correlations with template fit to extract bottom contribution at forward/backward rapidity.

- No significant nuclear modification on the **bottom production** in 200 GeV p+Au collisions.

- Analysis of charm/DY di-muons in p+Au data is underway.
Explore the **CNM** effect via $J/\psi$ and $\psi'$

- Mid-rapidity $\psi'$ $R_{dAu}$ measured at PHENIX in $d+Au$ collisions has different trend and magnitude of suppression versus $N_{\text{coll}}$ from the $J/\psi$ results.

- Similar **initial state** effect (shadowing, energy loss etc.) on $J/\psi$ and $\psi'$.

- Indications of impacts from **final state** effects cause the difference.

- Can we study this in forward/backward rapidity and different collision systems?
J/ψ and ψ’ measurement in p+Au collisions

• With improved mass resolution provided by FVTX, clear J/ψ and ψ’ identification via di-muon channel (1.2<|y|<2.2) in 200 GeV p+Al, p+Au and ³He+Au data.

• Clear J/ψ signal in both directions.

• Ψ’ is relatively suppressed in Au going direction.
Relative ratio of $\psi'$ to $J/\psi$ vs rapidity

- Centrality integrated relative ratio of $\psi'$ to $J/\psi$ VS rapidity.

- Forward rapidity: $J/\psi$ and $\psi'$ have similar suppression at PHENIX.

- Backward rapidity: strong relative suppression and comparable with LHC results.
Relative ratio of $\psi'$ to $J/\psi$ vs co-moving particle density

- The suppression of $\psi'$ to $J/\psi$ relative ratio at both RHIC and LHC scales with co-moving particle density.
Rapidity dependent $J/\psi$ $R_{AB}$ in $p+Al/Au$, $^3He+Au$ collisions

- Indication of $A$ dependent suppression of $J/\psi$ $R_{AB}$ at forward rapidity and smaller nuclear modification at backward rapidity.
$N_{\text{part}}$ dependent $J/\psi$ $R_{AB}$ in small systems

- **Forward rapidity**: indication of shadowing and energy loss may be the dominant effects of the suppression with relatively low hadron density.

- **Backward rapidity**: suggests “breakup” or co-mover may be the dominate effects with relatively high hadron density.
\( N_{\text{part}} \) dependent \( J/\psi \ R_{AB} \) in all systems

\[ \begin{array}{c}
\text{p/d/}^3\text{He/Cu/Au/U} \\
\text{Al/Cu/Au/U}
\end{array} \]

Backward rapidity

Forward rapidity

Inclusive \( J/\psi \) \( \sqrt{s_{NN}}\)\(=200 \text{ GeV} \)

-2.2<\(y<\)-1.2 (A-going)

1.2<\(\text{y}<\)2.2 (p/d/\(^3\text{He}-\text{going})

- Consistent \( N_{\text{part}} \) dependent \( J/\psi \ R_{AB} \) results at forward and backward rapidity in both small and large system.

- Final state effects such as color screening can not be ignored for the \( J/\psi \) measurements.
Do heavy quarks flow in small system?

- **Charged hadrons** flow at low $p_T$ in forward and backward rapidity in 200 GeV d+Au collisions.
Do heavy quarks flow in small system?

- **Charged hadrons** flow at low $p_T$ in forward and backward rapidity in 200 GeV d+Au collisions.

- Indication of **heavy flavor muons** may flow in forward and backward rapidity as well.
Heavy flavor measurements in Heavy Ion Collisions

• to study the Hot Nuclear Medium effects
• Do charm and bottom quarks flow?
• Forward and backward B to J/ψ $R_{AA}$
Study the **Hot Nuclear Matter** effect via D/B production

- From the PHENIX charm and bottom separated electron $R_{AA}$ results at mid-rapidity,
  - Bottom has similar suppression as charm for high $p_T$ region.
  - Bottom may be less suppressed than charm in the low $p_T$ region.
- Consistent with the mass/flavor dependent energy loss in the Quark Gluon Plasma (QGP):
  - $\Delta E_g > \Delta E_{u,d,s} > \Delta E_c > \Delta E_b$
- Do heavy quarks flow in Au+Au collisions?
- Do **bottom quarks** and charm quarks have the same flow?
Heavy flavor electron $v_2$ in Au+Au collisions

- New heavy flavor electron $v_2$ with (F)VTX is consistent with published results but with significantly improved stat. and sys. uncertainties.

Mid-rapidity $|y| < 0.35$

Select charm enriched sample

Simultaneously extract $v_2(c \rightarrow e)$ $v_2(b \rightarrow e)$

Select bottom enriched sample
Charm electron $v_2$ and Bottom electron $v_2$

- Significant charm electron $v_2$, smaller magnitude than charged hadron $v_2$ might due to charm decay kinematics.
- Indication of non-zero bottom $v_2$.
- Likely $v_2(b \rightarrow e) < v_2(c \rightarrow e)$. 

CIPANP2018  Xuan Li (LANL)
Ongoing analysis of forward $B$ to $J/\psi$ in $Au+Au$ collisions

- Analysis framework has been developed for the $B$ to $J/\psi$ studies in $p+p$ and $Cu+Au$ collisions.
- Analysis procedure has been updated and data processing is underway.
- The challenge is to minimize systematics.

Clear $J/\psi$ found in $Au+Au$ collisions
Summary

• Forward/backward di-muon correlations provide information about the sub-process of the charm/bottom production.

• Differential suppression of $\psi'$ to $J/\psi$ relative ratio and $J/\psi$ nuclear modification measurements in small system shows strong evidence of final state effects.

• Evidence of non-zero heavy flavor $v_2$ in small system.

• First bottom electron $v_2$ measurement at RHIC indicates flavor/mass dependent thermalization in the QGP.
Outlook

• Large data set in various types of heavy ion collisions collected at PHENIX provide opportunities to study
  – $\psi'$ to $J/\psi$ ratio in run14/16 Au+Au collisions to demonstrate hot nuclear matter effect like color screening in QGP.
  – Nuclear modification and thermalization properties of D/B separate single electrons/muons in run14/16 Au +Au collisions with higher statistics.
  – Forward/backward B to $J/\psi$ via di-muon channel in run14/16 Au+Au collisions to understand hot nuclear matter effect.
  – ...

• More to come soon.
Backup
Bottom cross section in p+p at PHENIX

• Consistent with NLO pQCD calculations
Possible contributions to the differential suppression

• Time spent inside the nucleus
  – Longer time and path length spent by the cc-bar in Au- (Al-) going direction than the p- going direction.
  – According to the crossing time $\tau$ dependent model fit on world wide data (PRC 87 (2013) 054910), very small contributions.
  – This effect can not explain the backward rapidity suppression.

• Co-movers absorption?
  – Charmonium can break up with the presence of co-movers.
  – Higher particle density in the Au- (Al-) going direction may cause larger suppression.
Relative ratio of $\psi'$ to $J/\psi$ VS rapidity

- Centrality integrated relative ratio of $\psi'$ to $J/\psi$ VS rapidity for p+Au, p+Al and d+Au (mid-rapidity).

- Result is generally consistent within significant statistical uncertainties with co-mover dissociation model.

- New model calculations? Plasma effect in central collisions?
Comparison with the LHC results

- Similar suppression trend for the rapidity dependence. More suppression in LHC especially in the forward rapidity?

- Larger co-mover contribution in the LHC era? Gluon saturation change spectroscopic charmonium states?
Study the **Hot Nuclear Matter** effect via D/B production

- Suppression of the **inclusive Heavy flavor** $R_{AA}$ provides evidence of strong coupling between the heavy flavor and medium.

![Graph showing $R_{AA}$ vs. $p_T$](image)

- Light hadron and **heavy flavor production** have different suppression, flavor dependent coupling?

- Need to separate **charm** and **bottom** and study the mass dependent quark energy loss.
Analysis strategy to separate charm and bottom

- Based on different lifetimes and decay kinematics.
- Decay length ($c\tau$):
  - Charm hadron: $c\tau(D^0)=123\mu m$, $c\tau(D^\pm)=312\mu m$.
  - Bottom hadron: $c\tau(B^0)=455\mu m$, $c\tau(B^\pm)=491\mu m$.
- Measure the Distance of Closet Approach (DCA) which is proportional to the decay length.
- Simultaneously extract statistically separated charm and bottom via Bayesian Unfolding.

2.00 < $p_T^e$ < 2.50

PRC 93, 034904 (2016)

DCA_T = L - R

Unfolding
Select charm (bottom) enriched sample based on electron DCA$_T$

- The fraction of charm and bottom varies in different DCA$_T$ region.
Charm and bottom enriched $v_2$ measurements

- Indication of mass/flavor dependence for $p_T>1.5$ GeV/c.
The Forward Vertex Detector (FVTX)

- **Sensor**
  - 2 columns of strips
  - 1664 strips per column
  - strip length 2.8 to 11.2 mm
  - 75 micron spacing
  - 48 wedges per disk (7.5°/sensor, 15°/wedge)
  - 0.5 mm overlap with adjacent wedges

- **FPHX Chip**
  - 1 column readout
  - 128 channels
  - ~70 microns channel spacing
  - Dimensions –9mm x 1.2 mm
