

AI/ML Surrogate-Accelerated Learning and Inference in Nuclear Data Problems

Ajeeta Khatiwada

Workshop for Applied Nuclear Data Activities (WANDA) 2026

Feb 11, 2026

LA-UR-26-20774

Motivation

Nuclear data problems are often:

- High-dimensional
- Computationally expensive

Many coupled reaction channels,
nuclei, energy regime etc.

Optimization and inference
can require 1000s to millions
repeated forward model calls

Traditional workflows:

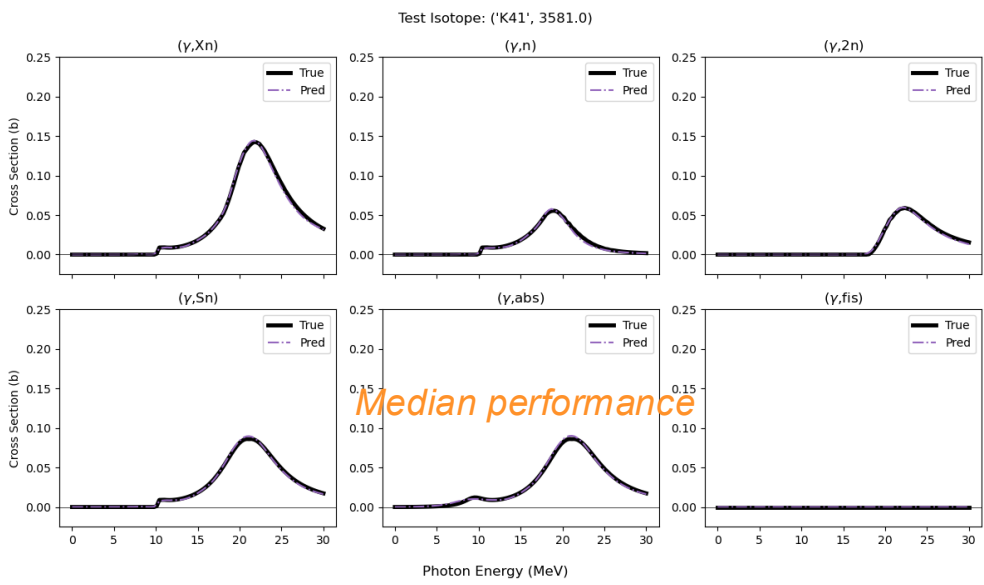

- Introduce biases and assumptions
- Limit optimization
- Limit full uncertainty exploration

Surrogate models can enable otherwise intractable learning and inference
with reduced computational load

Deep Learning Surrogate enabled MCMC evaluation of photonuclear cross sections

2.5M X speedup

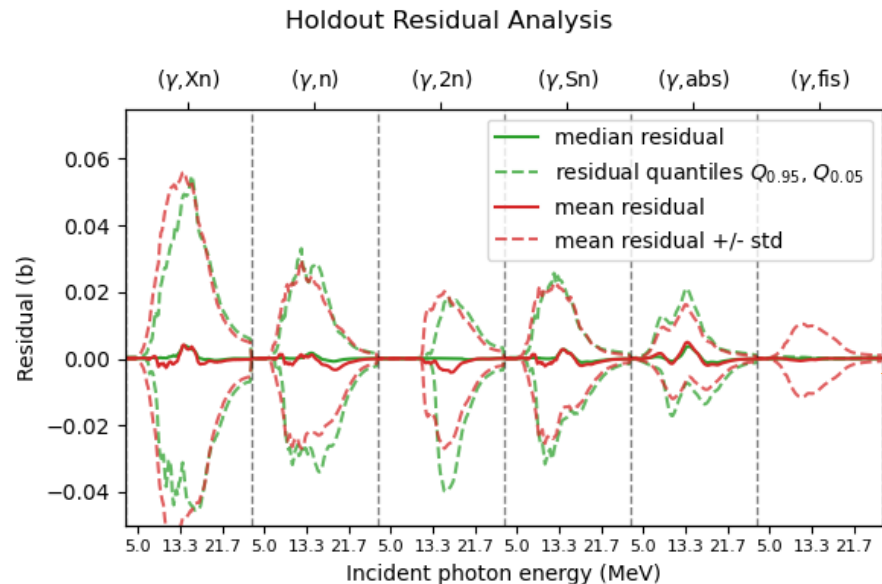

Emulates the theory models (CoH₃) accurately

Deep Learning Surrogate enabled MCMC evaluation of photonuclear cross sections

2.5M X speedup

Accurate predictions for held-out data outside of the training phase space

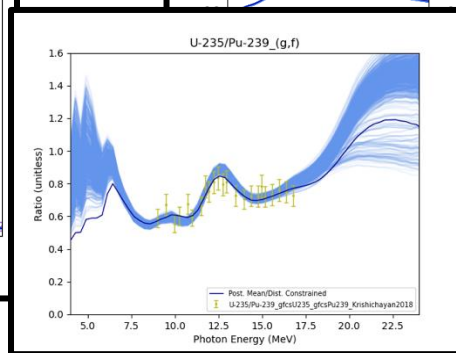

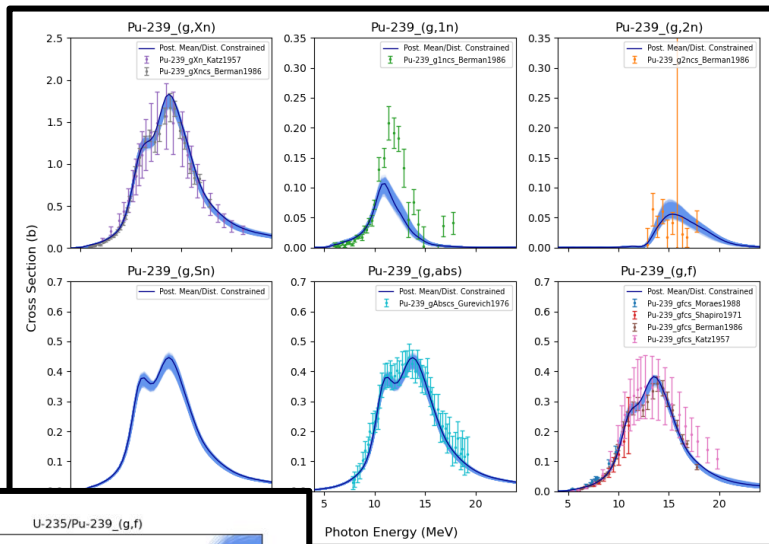

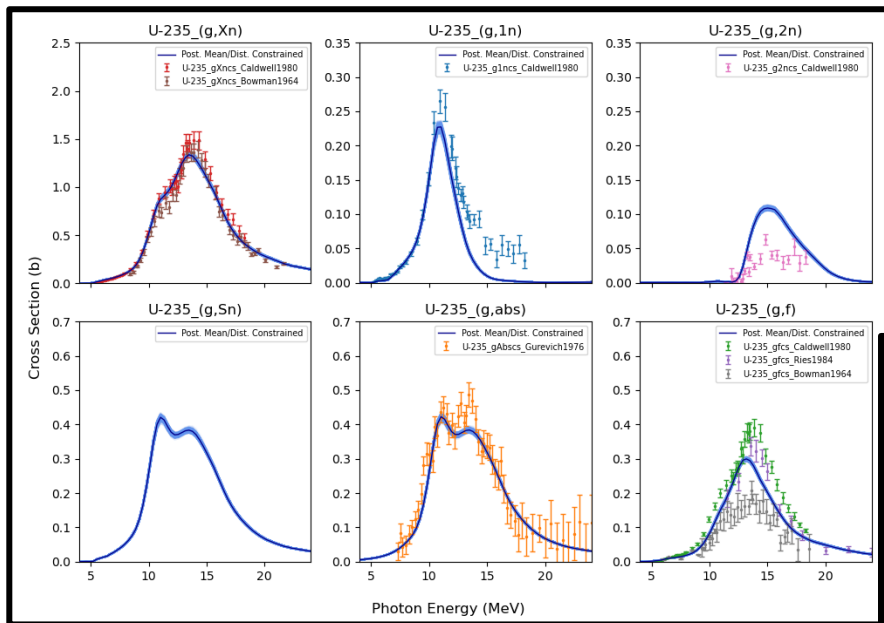

$\{N, \Gamma, \beta, \mathcal{F}\}$

Residuals are comparable to regions well represented in training set

Surrogate enables fast full-MC evaluation

Consistent posterior inference across coupled reaction channels, nuclei, and observables

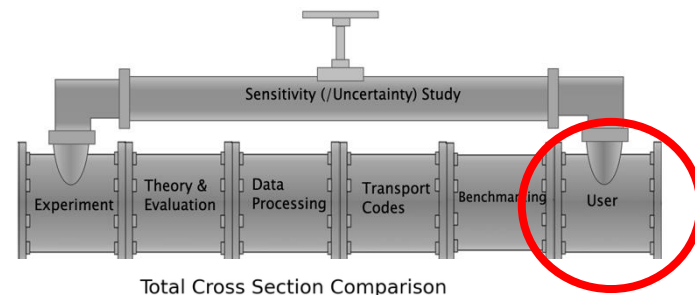

Especially valuable for photonuclear data with inconsistencies and data-model tension

Surrogate-enabled Reinforcement Learning for Energy Group Optimization

- Energy group structure used in nuclear data and transport calculations affects accuracy vs. runtime

618 energy group solve: 14 min vs. 30 group solve: 2 s

- Brute-force/group optimization are infeasible
- AI/ML surrogate modeling of the transport problem using CNN + LSTM and embedded inside a Reinforcement Learning framework for group optimization

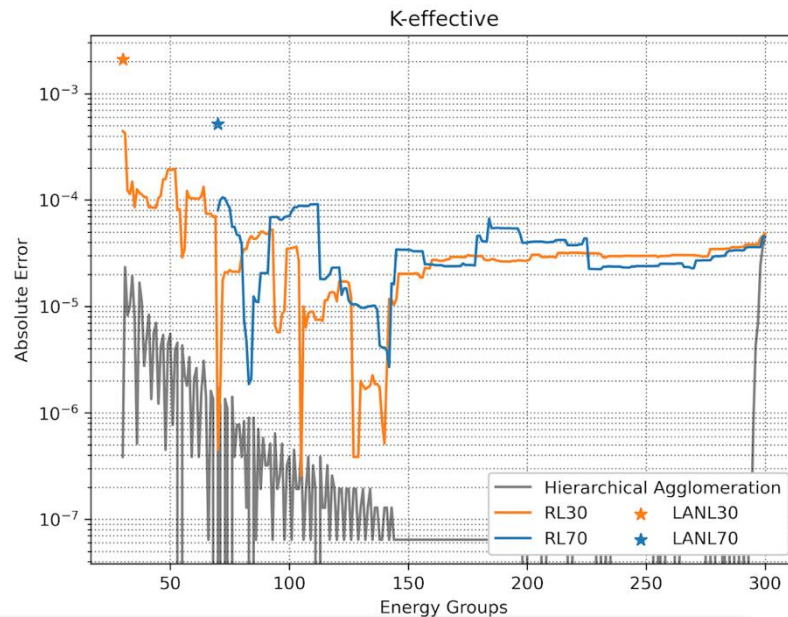

Total Cross Section Comparison

RL optimized group structure results

Supercritical Godiva, $G \in [30, 618]$, 73.367% / 98.019%

- Reusable CNN + LSTM based surrogate model for neutron transport.
- 1000+ days of RL training reduced to < 1 day training + 16 day data collection with surrogate
- RL optimized group structure outperforms commonly used ones

Key Finding: From speedup to capability

- Speed is means to an end; the goal is increased **capability**.
 - Optimization, UQ, inference previously infeasible become possible.
- Lessons:
 - Surrogates must be uncertainty aware
 - Hybrid workflows are often a good middle ground for preserving physics and making tiny steps
 - Physics still leads
 - Compatible with the ND culture of verification, validation and traceability.

Future direction: From one-off success to sustained capability

- How to go from one-off models to reusable infrastructure
 - For e.g., deploy CoH₃ surrogate model as a shared tool or framework that can be used across projects.
- From just speed metrics to decision-quality metrics
 - Metric for success cannot just be one thing. Accuracy, precision, defensibility etc. need to be factored.
- Ad-Hoc data to managed data generation
 - Training surrogates requires intentional, funded use of HPC or computational resources to generate high-value simulation data. This needs to be planned, not incidental.
- Novelty to Trust
 - UQ, validation protocols, and reproducibility build confidence, and investment need to be in these areas

The need

- Even small targeted investments in surrogate-embedded workflows have been shown to be effective in unlocking disproportionate gains in capability
- Methods fail when ML and nuclear physics are treated as siloed. Surrogates are not generic tools – their validity depends on physics assumptions, parameterization and uncertainty interpretation
- In practice, the people building and using these must be trained in both the nuclear data problem and the ML methods well enough to understand their failure modes
